

Probability Review 2

Lecture 2

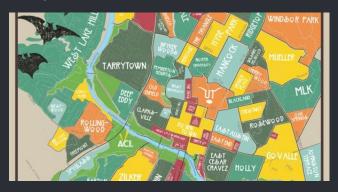

STA 371G

Find out the average house price in Austin.

Find out the average house price in Austin. How would you do that?

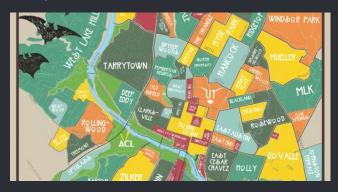

Find out the average house price in Austin. How would you do that?

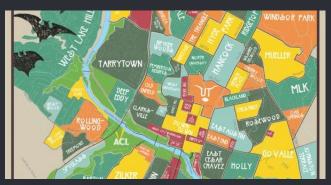

Look at each house price?

Find out the average house price in Austin. How would you do that?

Look at each house price? 360,000 houses in Austin!

Find out the average house price in Austin. How would you do that?

Look at each house price?
360,000 houses in Austin!
Can we do something smarter?

A smarter approach:

A smarter approach:

• Pick *n* houses randomly (e.g. n = 100)

A smarter approach:

- Pick *n* houses randomly (e.g. n = 100)
- Take the average of the prices of these *n* houses

A smarter approach:

- Pick *n* houses randomly (e.g. n = 100)
- Take the average of the prices of these *n* houses
- Hope that your estimate is close to the true price average.

A smarter approach:

- Pick *n* houses randomly (e.g. n = 100)
- Take the average of the prices of these n houses
- Hope that your estimate is close to the true price average.

Just like making polls to predict election results!

	Population	Sample	
Members	all house prices	prices you picked	
Average	population mean	sample mean	
Variance	population variance	sample variance	

	Population	Sample	
Members	all house prices	prices you picked	
Average	population mean	sample mean	
Variance	population variance	sample variance	

Estimating a population parameter (population mean) based on a sample statistic (sample mean).

Collecting a sample

Zillow.com, "Austin, TX."

- Click "More Map"
- Select 15 houses, note their prices in an R script.
- Do not discard any price, use the first 15
- Try to represent different regions

Collecting a sample

Your R script should look like this

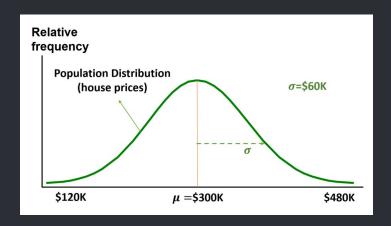

```
# Create a vector of house prices (You should have 15 price data)
sample house prices <- c(327000,276000,513000)</pre>
# Calculate sample statistics
sample mean <- mean(sample house prices)</pre>
sample variance <- var(sample house prices)</pre>
sample standard deviation <- sd(sample house prices)</pre>
# Sample mean of first 5 houses
sample mean 5 <- mean(sample house prices[1:5])</pre>
# Print them to console
cat("Sample Mean", sample mean)
cat("Sample Variance", sample variance)
cat("Sample Standard Deviation", sample standard deviation)
cat("Sample Mean of first 5 houses", sample mean 5)
```

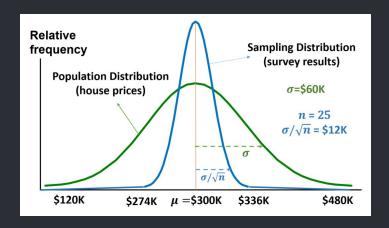

On Learning Catalytics, enter your results.

And here is what they look like...

Distribution of your answers → Sampling distribution

Statistic	Population	Sample Mean
Mean	μ	μ
Standard Deviation	σ	σ/√n

Assume $\mu = $300K$, $\sigma = $60K$.

	n	σ/√n	3 std. dev. range (99.7%)
Survey 1	25	\$12K	\$274K \$336K
Survey 2	100	\$6K	\$282K \$318K
Survey 3	3600	\$1K	\$297K \$303K

Let's compare sample mean of 5 houses vs 15 houses.

What do you expect to see?

t Distribution

We often do not know population variance and use sample variance instead.

In that case, the sample mean will have a *t* distribution.

Hypothesis: Average house price in Austin is \$1M.

Hypothesis: Average house price in Austin is \$1M. Your survey on 25 houses: Average house price is \$305K.

Hypothesis: Average house price in Austin is \$1M. Your survey on 25 houses: Average house price is \$305K.

Hypothesis: Average house price in Austin is \$1M. Your survey on 25 houses: Average house price is \$305K.

Questions, questions...

• Would you reject the hypothesis? Why?

Hypothesis: Average house price in Austin is \$1M. Your survey on 25 houses: Average house price is \$305*K*.

- Would you reject the hypothesis? Why?
- Is it possible that, out of bad luck, you picked the cheapest houses?

Hypothesis: Average house price in Austin is \$1M. Your survey on 25 houses: Average house price is \$305*K*.

- Would you reject the hypothesis? Why?
- Is it possible that, out of bad luck, you picked the cheapest houses?
- Would you be more comfortable with your conclusion if you had 1000 houses in your survey?

Hypothesis: Average house price in Austin is \$1M. Your survey on 25 houses: Average house price is \$305K.

- Would you reject the hypothesis? Why?
- Is it possible that, out of bad luck, you picked the cheapest houses?
- Would you be more comfortable with your conclusion if you had 1000 houses in your survey?
- When should you reject the hypothesis? When not?

Your sample mean: \$305K.

Your sample mean: \$305K.

 H_0 : $\mu = $1M$ (Null hypothesis)

 $H_1: \mu < $1M$ (Alternative hypothesis)

Your sample mean: \$305K.

 H_0 : $\mu = $1M$ (Null hypothesis)

 $H_1: \mu < $1M$ (Alternative hypothesis)

The *P*-value is "the probability of observing such an extreme (\$305K or less) sample statistic given the null hypothesis is true."

Your sample mean: \$305K.

 H_0 : $\mu = $1M$ (Null hypothesis)

 $H_1: \mu < $1M$ (Alternative hypothesis)

The *P*-value is "the probability of observing such an extreme (\$305K or less) sample statistic given the null hypothesis is true."

• *P*-value $\leq \alpha$, reject the null hypothesis

Your sample mean: \$305K.

 H_0 : $\mu = $1M$ (Null hypothesis)

 $H_1: \mu < $1M$ (Alternative hypothesis)

The *P*-value is "the probability of observing such an extreme (\$305K or less) sample statistic given the null hypothesis is true."

- *P*-value $\leq \alpha$, reject the null hypothesis
- *P*-value > α , reject the null hypothesis

Your sample mean: \$305K.

 H_0 : $\mu = $1M$ (Null hypothesis)

 $H_1: \mu < $1M$ (Alternative hypothesis)

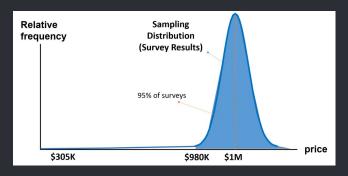

The *P*-value is "the probability of observing such an extreme (\$305K or less) sample statistic given the null hypothesis is true."

- *P*-value $\leq \alpha$, reject the null hypothesis
- *P*-value > α , reject the null hypothesis

 α is usually chosen as 0.05 prior to sampling.

If the null hypothesis were true...

If the null hypothesis were true...

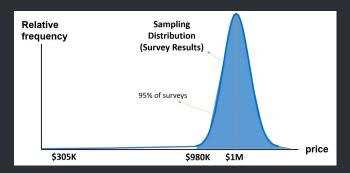

If the null hypothesis were true...

P-value is smaller than 10^{-100} , while $\alpha = 0.05$.

If the null hypothesis were true...

P-value is smaller than 10^{-100} , while $\alpha = 0.05$. Rather than thinking you are cursed, you simply reject the hypothesis!

Learning Catalytics...

Learning Catalytics...

Your sample mean = \$305K.

Learning Catalytics...

Your sample mean = \$305K.

 H_0 : Average house price is \$390K. Would you reject the hypothesis? P-value = 0.01, α =0.05

Learning Catalytics...

Your sample mean = \$305K.

 H_0 : Average house price is \$390K. Would you reject the hypothesis? P-value = 0.01, α =0.05

 H_0 : Average house price is \$320K. Would you reject the hypothesis? P-value = 0.34, α =0.01

Learning Catalytics...

Your sample mean = \$305K.

 H_0 : Average house price is \$390K. Would you reject the hypothesis? P-value = 0.01, α =0.05

 H_0 : Average house price is \$320K. Would you reject the hypothesis? P-value = 0.34, α =0.01

Sample mean is not equal to the population mean, but "close."

Sample mean is not equal to the population mean, but "close." Confidence interval is a range that includes the population mean with a certain level of "confidence."

Sample mean is not equal to the population mean, but "close." Confidence interval is a range that includes the population mean with a certain level of "confidence."

Add the following to your R script

```
# Calculate 95% confidence interval (default)
avg_price_ci_95 <- t.test(sample_house_prices)
# Calculate 99% confidence interval
avg_price_ci_99 <- t.test(sample_house_prices, conf.level = 0.99)
# Display results
cat("95% confidence interval is:", avg_price_ci_95$conf.int)
cat("99% confidence interval is:", avg_price_ci_99$conf.int)</pre>
```
